Visualizing Champion Win Rates in High-Ranked League of Legends

Introduce

As a high-ranked League of Legends player, I have a strong interest in understanding the dynamics of the game's meta at the highest levels of competition. This project focuses on creating a data representation based on two weeks of win rate rankings for champions, specifically collected from high-ranked players on the op.gg platform.

How to collect the data?

From patch 14.25 to 15.2, we focused on high-ranked solo/duo queue data from the Diamond tier and above, using information from the op.gg platform. The data collected includes

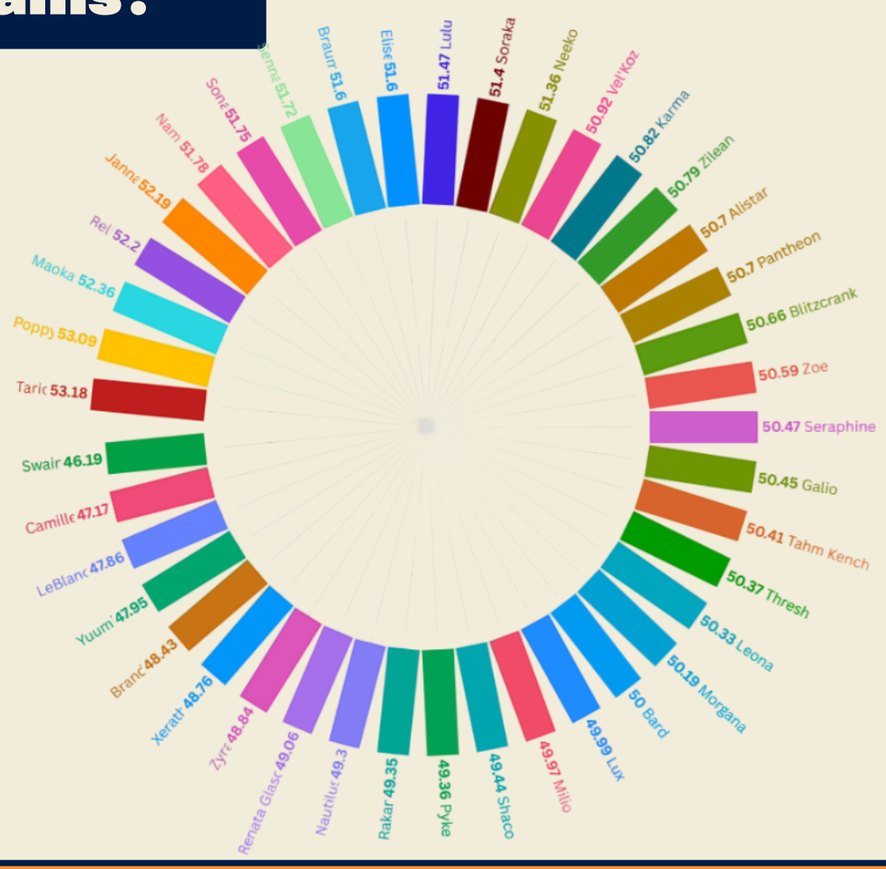
x LEAGUE OF LEGENDS

"I am a gamer, and I hope to see the changes in champions data in recent versions in a more intuitive way"

"I am a game designer, and I can more easily observe which champions need to be buffed or nerfed"

What My Dataset Contains?

My dataset consists of data collected from the 'op.gg' platform for solo/duo ranked games in the Diamond tier and above across three patches. It includes champion names, win rates, patch versions, and tier information. This structured data served as the basis for analyzing champion performance trends and creating visualizations to explore changes over time. The right graphic is champion's win rate in version 15.1



In Legend of League, only 3% of players in this game are above the Diamond segment, So these numbers are pretty representative!

Data Visualization

This visualization uses small-multiple line charts to show win rate trends for individual champions across three patches . Each chart focuses on a single champion, with consistent axes for easy comparison. The purpose is to highlight how win rates evolve over time, making it clear which champions are stable, improving, or declining in performance.
Key Features: Champion-Specific Charts, Consistent Axes, Color Coding, Data Points

What's the steps of creative process?

Data Collection

I collected data from the op.gg platform for solo/duo ranked games in the Diamond tier and above, focusing on three consecutive patch versions. The data included champion names, tier rankings, and win rates across these patches.

Data Organization

After collecting the data, I organized it into a CSV file to ensure it was structured and easy to analyze. This format allowed seamless integration with visualization tools for further processing.

Initial Sketches

Based on the methods taught in class, I decided to use the small-multiple approach to represent the changes in win rates for each champion across different patches. This method allows for easy comparison and highlights individual trends effectively.

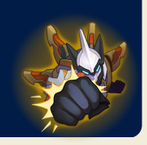
Final Visualization

I combined line charts and bar charts for the final visualization. Line charts clearly display the trends in win rates over time, while bar charts provide insights into how win rates change across different patches. This combination offers a comprehensive view of the data.

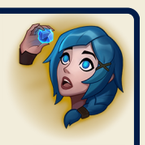
Insights & Design Justification

Insights

Some champions experience dramatic win rate fluctuations across patches, such as Shaco andBrand seeing significant boosts in newer versions. Many champions also see large win rate declines, like Galio and Zoe.
Designers likely adjust champions with win rates that are too high, as seen with Elise performing very well in 15.1 but falling below 50% in 15.2.
I also found the small-multiple method useful for comparing these champion trends. For datasets with many versions, you noted chart race animations could effectively highlight performance trends.



Design Justification



I chose to combine line charts and bar charts, presented as a 'small multiple' layout, for the final representation. This approach effectively conveys trends over time while providing contextual information, such as win rates and patch updates. Although I considered other ideas, they lacked the clarity needed to highlight changes in win rates and their relationship to other factors. Line charts offer an intuitive way to observe trends, while bar charts add depth by showcasing each champion's popularity and priority.
